Forklift Control Valve

Forklift Control Valve - The first automated control systems were being utilized over two thousand years ago. In Alexandria Egypt, the ancient Ktesibios water clock made in the 3rd century is thought to be the very first feedback control equipment on record. This particular clock kept time by way of regulating the water level inside a vessel and the water flow from the vessel. A popular design, this successful tool was being made in the same fashion in Baghdad when the Mongols captured the city in 1258 A.D.

Different automatic machines through history, have been utilized to be able to carry out particular jobs. A common style utilized in the 17th and 18th centuries in Europe, was the automata. This particular device was an example of "open-loop" control, comprising dancing figures that will repeat the same task over and over.

Feedback or "closed-loop" automatic control tools consist of the temperature regulator found on a furnace. This was developed in the year 1620 and accredited to Drebbel. Another example is the centrifugal fly ball governor developed in the year 1788 by James Watt and used for regulating steam engine speed.

J.C. Maxwell, who discovered the Maxwell electromagnetic field equations, wrote a paper in 1868 "On Governors," which can describe the instabilities demonstrated by the fly ball governor. He utilized differential equations to describe the control system. This paper exhibited the usefulness and importance of mathematical models and methods in relation to comprehending complicated phenomena. It likewise signaled the beginning of mathematical control and systems theory. Previous elements of control theory had appeared earlier by not as convincingly and as dramatically as in Maxwell's study.

In the next 100 years control theory made huge strides. New developments in mathematical methods made it possible to more accurately control considerably more dynamic systems as opposed to the original fly ball governor. These updated techniques comprise various developments in optimal control in the 1950s and 1960s, followed by development in robust, stochastic, adaptive and optimal control techniques during the 1970s and the 1980s.

New applications and technology of control methodology have helped produce cleaner auto engines, cleaner and more efficient chemical methods and have helped make space travel and communication satellites possible.

Initially, control engineering was practiced as just a part of mechanical engineering. Control theories were originally studied with electrical engineering in view of the fact that electrical circuits can simply be described with control theory methods. At present, control engineering has emerged as a unique practice.

The first controls had current outputs represented with a voltage control input. To be able to implement electrical control systems, the proper technology was unavailable at that time, the designers were left with less efficient systems and the alternative of slow responding mechanical systems. The governor is a very effective mechanical controller that is still usually utilized by several hydro plants. In the long run, process control systems became obtainable before modern power electronics. These process controls systems were often used in industrial applications and were devised by mechanical engineers using hydraulic and pneumatic control machines, lots of which are still being used today.
